

“Porsche is committed to a double-e path: e-mobility and eFuels”

11/07/2022 CEO Oliver Blume talks about the future of combustion engines, eFuels and Porsche's electric strategy.

Porsche CEO Oliver Blume on the future of combustion engines:

“E-mobility is of the highest priority for us. At the same time, we continue to build modern combustion engines. The 911 is more popular than ever with customers. Over the coming years, we will offer a very sporty hybrid setup for the 911, as many are familiar with from the motorsport context. These resolute climate protection steps are good. I support the German government's open approach with regard to the technology and the coalition's compromise to incorporate e-fuels as part of the solution. Technology bans act as a brake on innovation. Porsche is committed to a double-e path: e-mobility and eFuels.”

In 2030, more than 80 percent of delivered cars are set to be all-electric:

"Among the traditional automakers, we have a very progressive electric strategy. Our ambition is for more than 80 percent of vehicles delivered to customers in 2030 to be all-electric. Our first all-electric Taycan sports car is already a huge success. Last year, we managed to double deliveries over the strong previous year to more than 41,000 vehicles. That puts the Taycan on a par with our iconic 911. We see ourselves as a pioneer in sustainable mobility."

Why eFuels make all "normal and old" cars cleaner:

"Climate protection has to be seen holistically. That's why we need to be open in terms of technology. Electromobility is an important track. At the same time, there are more than a billion existing vehicles worldwide. They will be on the roads for decades to come. EFuels are an effective, complementary solution in this regard. They can enable all vehicles to play a role in reducing CO2 – regardless of the powertrain type. Combustion engines can be powered with e-fuels in a virtually carbon-neutral manner. They don't have to be converted or retrofitted for it. EFuels can be offered as an admixture or alone at all filling stations. We have to offer an option to the owners of existing vehicles too."

What will a liter of eFuel will cost:

"That depends on the level of future production. If produced on an industrial scale, prices of less than \$2 per liter could be possible. The important thing is that synthetic fuels are produced sustainably and in places in the world where renewable energy is abundant – then the higher energy input for production is irrelevant. EFuels produced from water and the carbon dioxide extracted from the air for automobiles, planes and ships have the advantage over pure hydrogen that they can be transported more easily."
